

Table S1

Preregistration Deviations Table

Deviations					
#	Details		Original Wording	Deviation Description	Reader Impact
1	Type	Sample	“Companion articles will be selected based on the following criteria, modified from the criteria used by O’Mahony (2023). <i>Journal</i> - the companion articles must be selected from the same journal as the Registered Report. <i>Timeframe</i> - The companion articles should be selected from the same issue as the Registered Report. If no companion article is available in the same issue, we will examine the prior issue. If none is available in the prior issue, we will examine the subsequent issue. We will continue this process of alternately looking through the next prior and subsequent issues until a companion is identified that was published in the same year as the Registered Report. <i>Topic</i> - The companion articles should generally be the same substantive topic of the Registered Report, broadly conceived. <i>Topic</i> will be coded as 1 - very similar (e.g., both focused on risk factors related to depression), 2 - mostly similar (e.g., both focused on risk factors for psychopathology), or 3 - somewhat	We had specified that we would use a process modified from the criteria used by O’Mahony (2023), which sought to make matches based on journal, timeframe, topic, and design. We immediately ran into problems with this approach. Primarily, O’Mahony (2023) only matched two article types (Registered Reports and traditional articles) whereas we matched three; those two in addition to preregistered articles. This additional article type made the matching process exponentially more difficult, and in some cases impossible. Accordingly, we opted to formally match only on journal and year of publication. Topic and design were considered when selecting articles, and all efforts were made to ensure similarities, but doing so was often not possible.	Moderate impact: The original plan was much more rigorous, and would have led to a closely matched set of articles. As noted, it simply was not feasible. The resulting dataset remains very strong, as journal and timeframe are arguably the most crucial elements to match on. We discuss the issue of matching articles more in the Discussion section.
	Reason	Plan not possible			
	Timing	During data collection			

			similar (e.g., both are related to psychopathology). Ideally, all included articles would have a rating of 1 or 2, but 3s will be acceptable if needed to ensure that we select articles published in the same year as the Registered Report. <i>Design</i> - The companion articles should generally be the same design, for example experimental, intervention, observational, or longitudinal. <i>Design</i> will be coded as 1 - very similar, 2 - somewhat similar, or 3 - not similar. Ideally, all included articles would have a rating of 1 or 2, but 3s will be acceptable if needed to ensure that we select articles published in the same year as the Registered Report.”		
2	Type Reason Timing	Sample Plan not possible During data collection	“First, an additional group of 100 traditional articles published in 2010 will be selected from the same journals as the Registered Reports. Starting with the first issue published in 2010, we will identify an empirical article that matches the previously selected companion traditional articles based on <i>Topic</i> and <i>Design</i>, using the same criteria described above. The selected articles must have a score of at least 2 for each of <i>Topic</i> and <i>Design</i> to be included.”	Our plan was to include 100 articles in this category to align with the focal article set, but three journals (<i>Collabra: Psychology</i>, <i>Cognitive Research: Principles and Implication</i>, and <i>Nature Human Behavior</i>) did not exist in 2010, so no matches were possible. The final sample for this article type was 82.	Minimal impact: The result is a somewhat smaller sample for a non-central analysis of the paper that was not based on inferential statistics.
3	Type Reason Timing	Sample Other (Please Explain) During data collection	“Additionally, we will partially address the influence of journal policies by conducting an analysis of journal policies as indicated on the journal homepages in June 2026.”	Policies were collected in August 2026, just because we were running behind.	No impact: The plan was to collect current policies, and not policies at the time of the articles submission or acceptance (which was not possible). Given that there

					would already be a time disconnect, a couple more months is not meaningful.
4	Type	Analysis	“The focal set of 300 articles will be coded by the four raters, arranged in two teams of two raters each. Each team will code 125 unique articles, with the remaining 50 articles being coded by all four raters. The articles coded by all four raters will be interspersed across the coding period to assess rater drift. Percent agreement will be assessed for each batch, and the raters for that batch will meet to resolve discrepancies via discussion.”	After establishing reliability, the first author coded all articles with the fourth author coding 20% for reliability. This change was made due to the highly compressed schedule for completion of the project and the difficulty of working around all of the authors’ schedules during the summer months.	Moderate impact: The original plan would have led to a dataset with fewer errors, given that all disagreements would be resolved. Reliability was still assessed for a random subset and found to be good, so risk of bias is low.
	Reason	Plan not possible			
	Timing	After data access			
5	Type	Variables	“Raters will code for how difficult it was to determine their rating, which also can serve as a useful indicator of their confidence in their ratings. We will use the system from O’Mahony (2023): 1 - Very easy, 2 = Somewhat easy, 3 = Somewhat difficult, and 4 = Very difficult. Raters will provide a global rating for difficulty, rather than for each section.”	Difficulty ratings were still conducted, but because of the change in the rater plan (see #4), they no longer served the same purpose of indicating confidence in ratings, so were not used in the manuscript.	Minimal impact: This difficulty analyses were not central to the article.
	Reason	Other (Please Explain)			
	Timing	After data access			
6	Type	Analysis	“Second, although Registered Reports that include a mix of registered and non-registered studies are excluded from the primary analyses, all articles coded as these “partial” Registered Reports will be coded separately at the study level, using the same coding process as the primary analyses, to determine any possible within-article variations in exploratory research based on study type. This analysis will only be based on Registered Reports, and thus inferences will be limited to that context. Because these articles will be	The sample of partial Registered Reports were indicated in the dataset, but were not analyzed in the paper. This decision was made for the sake of time and because this was a non-central exploratory analyses.	Minimal impact: The related analyses were non-central exploratory analyses.
	Reason	Plan not possible			
	Timing	During data collection			

			identified through the coding process, the sample size is unknown.”		
7	Type	Sample	“Third, to assess the implications of using journals that publish Registered Reports as our starting point for article selection, we will select an additional sample ($n = 25$) of traditional articles from journals that do not publish Registered Reports.”	We selected 30 articles, instead of 25, because there were 30 journals in the final dataset and this allowed us to have one article per journal.	No impact: we coded more articles than planned.
	Reason	Other (Please Explain)			
	Timing	Before data collection			

Unregistered Steps

#	Details		Original Wording	Unregistered Step Description	Reader Impact
1	Type	Sample	Not addressed	“The first article listed alphabetically for each of the 30 journals in the primary article set was selected. These 30 articles were the basis for finding a match in non-Registered Report journals, based on the criteria for matches described above.”	No impact: There is no inherent bias in this article selection process.
	Timing	Before data collection			
2	Type	Analysis	Not addressed	“As a secondary sensitivity test, we also conducted non-registered tests that accounted for clustering based on the matching procedure (e.g., treating a Registered Report and its traditional article match as clustered), given that the selection process was non-independent.”	No impact: This is an additional robust test, conducted beyond what was already planned.
	Timing	After data access			
3	Type	Analysis	Not addressed	“As previously noted, a small number of journals have published an outsized number of Registered Reports. We compared the three most prolific journals (<i>Cortex</i> , <i>Nature Human Behavior</i> , and <i>Journal of Experimental Social Psychology</i>), which accounted for 38%	No impact: This is an interesting additional analysis that was clearly labeled and treated as exploratory.
	Timing	After results known			

				of Registered Reports, with all others (Figure 4). One question we wondered about is whether reporting of exploratory research was higher in Registered Reports and preregistration in the three prolific journals compared to the others.”	
4	Type	Sample	Not addressed	After the screening was complete, we decided to omit articles from <i>Advances in Methods and Practices in Psychological Science</i> because it is a methods journal that publishes substantive Registered Reports, and we thought it would be difficult to locate appropriate matches.	Minimal impact: This decision reduced the total number of journals included, which was already arbitrary, by one.
	Timing	After data access
